Alzheimer MRI Screening – Patient Report

Patient: dcdbjjkds (ALZ-1F99DE) | Scans on record: 2

Scan history

#	Date	Predicted stage	Confidence	Main region	Status
1	2026-11-03	NonDemented	96.2%	ventricular / central	pending
2	2026-11-03	MildDemented	100.0%	ventricular / central	pending

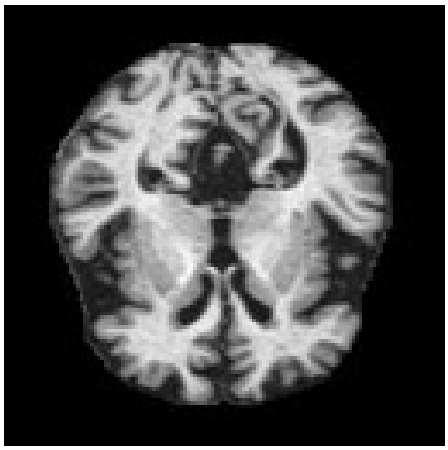

Overall: from NonDemented (2026-11-03) to MildDemented (2026-11-03) the model's predicted stage has increased (progressed).

Scan 1 of 2 – 2026-11-03

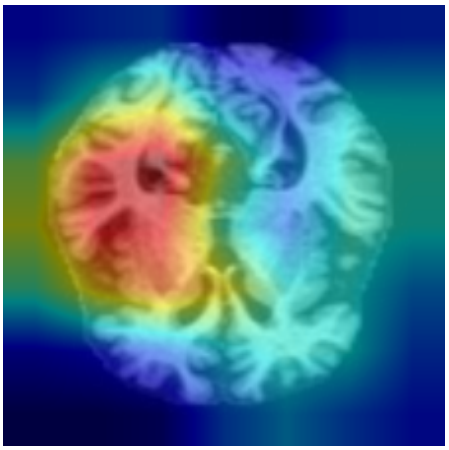

Case: CASE-1793714733-5AD5 | Date: 2026-11-03 14:05 UTC

Predicted stage: NonDemented (96.2%)

NonDemented	96.2%
VeryMildDemented	0.5%
MildDemented	3.3%
ModerateDemented	0.0%

Input MRI

Grad-CAM heatmap

Brain region contributing most: ventricular / central

Reason for detection

The model classified this scan as NonDemented with high confidence (96.2%) because its attention was concentrated in the central region near the ventricles. This is consistent with no notable atrophy pattern, which is a pattern typically seen in nondemented cases.

Summary

The model predicts the patient is NonDemented with high confidence.

Imaging findings

The model's prediction is consistent with the patient's stage of 'NonDemented'. The probabilities for other stages are low, with 'VeryMildDemented' being the second most likely outcome at 0.5%. The model's confidence in its prediction is high, with a confidence band of 'high'.

Interpretation

The model's prediction should be treated as accurate given its high confidence. However, the presence of a low probability for 'VeryMildDemented' suggests that the model is not entirely ruling out this possibility. Further investigation may be warranted to confirm the model's prediction.

Trend

No earlier scan is on record for this patient.

Limitations

The model's accuracy may be limited by the quality and quantity of the training data. The model's reliance on a single scan may also introduce limitations, as the patient's condition may have changed since the scan was taken.

Suggested next steps

- No imaging pattern suggestive of dementia was flagged by the model.
- Continue routine check-ups as advised by a clinician.
- This is a model screening output; a qualified clinician must confirm any finding.

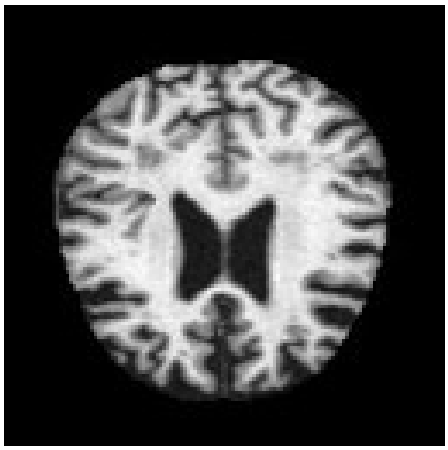

Status: pending.

Scan 2 of 2 (latest) – 2026-11-03

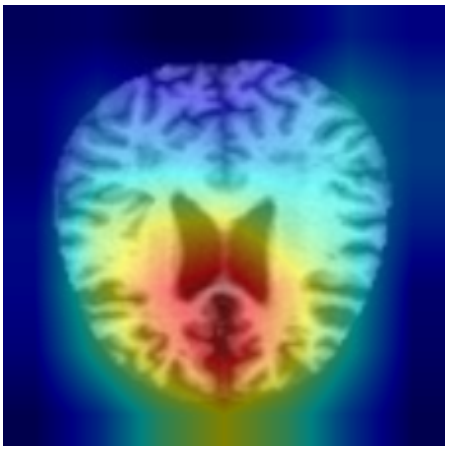

Case: CASE-1793716120-2877 | Date: 2026-11-03 14:28 UTC

Predicted stage: MildDemented (100.0%)

NonDemented	0.0%
VeryMildDemented	0.0%
MildDemented	100.0%
ModerateDemented	0.0%

Input MRI

Grad-CAM heatmap

Brain region contributing most: ventricular / central

Reason for detection

The model classified this scan as MildDemented with high confidence (100.0%) because its attention was concentrated in the central region near the ventricles. This is consistent with moderate structural changes, including some enlargement of the ventricles, which is a pattern typically seen in milddemented cases.

Summary

The model predicts the patient's dementia stage as MildDemented with high confidence.

Imaging findings

The patient's brain MRI scan is consistent with a diagnosis of MildDemented, with a 100.0% confidence level. The model's predictions are based on the probabilities of the patient being in each dementia stage, with MildDemented being the most likely.

Interpretation

The model's prediction of a higher stage compared to the previous scan (NonDemented on 2026-11-03) is consistent with the patient's disease severity increasing since the previous scan. This is a follow-up report, and the overall pattern across the scans on record is one of progression.

Trend

The predicted stage moved from NonDemented (2026-11-03) to MildDemented, 2 stage(s) higher: the model's predicted disease severity has INCREASED (progressed) since the previous scan. The overall pattern across the scans on record is one of progression. No earlier scan is on record.

Limitations

The model's predictions are based on a single scan, and further evaluation is needed to confirm the results. The model's confidence level is high, but it is essential to treat the result with caution due to the complexity of the patient's condition.

Suggested next steps

- Consult a neurologist for clinical evaluation and cognitive testing.
- Discuss support planning and home safety with the care team.
- The predicted stage has advanced since the previous scan; earlier review by a neurologist is advisable.
- This is a model screening output; a qualified clinician must confirm any finding.

Status: pending.
